

Figure D. When together is worse, and the creature that eventually disappears

PROVISIONAL: evidence from unmerged PR #27 (Lane 6) @ efa8999 and PR #30 (Lane 7, HR-009) @ 4e74822.

The new findings are proposed claims, not ledger entries. Ledger statuses (C038, C041) checked against research/claims.md @ 76ee3a6.

a S101 under port injury (I004): an ordinary response (cells: Orbia alive at the end)

Pair = partners alone in 58 of 60 runs: the uninjured partner survives on its own (L6-008 I004: H0). The 2 dashed mismatches at s 0.05 are the split half being fragile; a lone, relaxed Orbiu survives 0.05 (Lane 4, L4-002).

b S101 under frontal addition (I003): worse together at s 0.2-0.3, in a 128^2 world

128^2 WORLD ONLY. Lane 6 (PR #27 @ efa8999; L6-009, not yet proposed): the gap pulse splits the pair into two free Orbia. At s 0.2 they die when they later collide on the 128^2 torus; in a 256^2 world they end as two Orbia (5 of 5, exploratory). So s 0.2 is a finite-world artefact, and s 0.3 is world- and placement-dependent.

c, d S102 at its registered rule (R 13, T 10 only): a chaotic transient, not one death time

R 13, T 10 ONLY. Lane 3 (PR #29 @ 8c3c082) reproduces these deaths at R 13, T 10, but no copy ends when either knob is refined: 0 of 29 runs at R 26 and 0 of 3 at R 39 (T 10); 0 of 24 at T 20 and 0 of 24 at T 40 (R 13), to 8000 tu. The collapse is an effect of the R 13, T 10 discretisation, not a lifetime of the rule. Refined runs are censored, not shown to be attractors.
